

AI lead nurturing and qualification

Purpose

The AI chatbot acts as a consultative sales representative and continuously reassesses a lead from the complete available conversation. The workflow is business-agnostic: its language, offerings, qualification questions, and value mapping come from the AI node's training text, the configured Google Spreadsheet, the product catalog, and the customer's actual messages rather than hard-coded industry terms.

The customer-facing reply and the internal CRM assessment are separate AI operations. Customers receive a natural, concise reply; internal scores, criteria, and Kanban changes are never disclosed in chat.

Dynamic inputs and fallback order

1. Conversation history is the evidence of the lead's stated interests, problem, intended use, urgency, budget, authority, and requested next step. Qualification uses up to the latest 30 inbound and outbound messages even if the AI node's customer-reply history setting is zero.
2. Google Spreadsheet knowledge supplies niche-specific products, services, descriptions, prices, policies, and sales facts. Retrieval selects records relevant to the current customer message.
3. AI node training text defines the business, tone, offerings, boundaries, and any niche-specific sales guidance.
4. Product catalog supplements explicitly requested product details and prices.

Spreadsheet access is optional. A private, malformed, slow, or unavailable sheet is logged but does not stop the response, nurturing, scoring, or Kanban workflow. In that case the chatbot continues from training text, catalog data when available, and conversation history. Without an exact matching knowledge price, estimated value remains zero rather than being guessed.

Nurturing behavior

For every eligible AI turn, the chatbot:

- Uses already-known conversation facts and avoids repeating answered questions.
- Relates only relevant products or services to the customer's stated goal.
- Asks at most one concise question about the most important missing detail: need, intended use, timing, budget, or decision readiness.
- Remains helpful and non-pressuring and never exposes qualification mechanics.
- Continues normally when the Spreadsheet, catalog, qualification API call, or Kanban persistence is temporarily unavailable.

Qualification score

The internal score is normalized to 0–100 using these criteria:

Criterion	Maximum	Evidence examples
Product/service interest	25	Names an offering, asks about features, pricing, availability, or suitability
Explicit need/problem fit	25	Describes a goal, pain point, use case, desired outcome, or requirements
Buying intent/next step	20	Requests a quote, demo, order, consultation, proposal, or contact
Timing/urgency	15	Gives a deadline, purchase window, event date, or urgency
Budget/decision readiness	15	Shares budget constraints, confirms affordability, identifies an approver, or has authority

Only customer-supported facts count; missing details score zero and are not inferred. The application marks a lead Qualified only when all of the following are true:

- Score is at least 65.
- The customer has demonstrated interest in a product or service.
- The customer has expressed a relevant need or use case.

The assessment also updates Kanban probability with the score and derives priority from the conversation. It never automatically changes Won or Lost opportunities, and it respects the Kanban stage lock. Qualified leads are not automatically downgraded by a later weak or ambiguous message.

Estimated lead value

Estimated value is conservative and traceable:

1. Identify the particular product or service supported by the conversation.
2. Find an exact price for that same offering in retrieved business knowledge.
3. Write that price and its currency to the opportunity value field.
4. If the match or price is absent or ambiguous, leave the value unchanged (or zero for a new lead).

The system must not use an unrelated item's price, invent a price, treat the customer's budget as the sale value, or estimate from general model knowledge.

Kanban persistence and safety

The chatbot finds an opportunity by owner and chat/mobile identity, creating a New Lead opportunity if the Kanban tables are available but no opportunity exists. Each completed analysis updates probability and priority, optionally writes a knowledge-backed value, and moves an eligible opportunity to Qualified. An audit note records the score, matched interest, and brief reasoning.

All qualification and persistence errors are isolated from message delivery. This fail-open behavior is intentional: sales conversations and nurturing must continue even when enrichment infrastructure is unavailable.
